Technological development in electric-field control of magnetic properties is strongly demanded to realize novel spintronic devices with ultralow operating power. Voltage-controlled magnetic anisotropy (VCMA) effect in an ultrathin ferromagnetic metal layer¹² is the most promising approach, because it can be applied in MgO based magnetic tunnel junction (MTJ). We have demonstrated fast speed response of VCMA effect through the voltage-induced ferromagnetic resonance⁵ and pulse-voltage induced dynamic magnetization switching⁴ so far. One of the outstanding technical issues in the VCMA effect is the demonstration of scalability. For example, for the development of G-bit class memory applications, high VCMA coefficient of more than 1000 fJ/Vm is required with sufficiently high thermal stability. However, the VCMA effect with high speed response is limited to be about 100 fJ/Vm at present.⁵

In this study, we investigated the VCMA effect in an ultrathin Fe layer sandwiched between epitaxial Cr(001) buffer and MgO(001) barrier layers.⁶ High interface anisotropy energy, Kᵢ₀ of about 2 mJ/m² was recently demonstrated in Cr/ultrathin Fe/MgO structure,⁷ probably due to the atomically flat interfaces and suppression of surface segregation from the buffer material. We applied this structure in the voltage-driven MTJ and performed systematic investigations on perpendicular magnetic anisotropy (PMA) and VCMA effect through the tunnel magnetoresistance (TMR) properties. Fully epitaxial MTJ of MgO seed (3 nm)/Cr buffer (30 nm)/ultrathin Fe (tFe)/MgO (tMgO)/Fe (10 nm)/Ta/Ru were deposited on MgO (001) substrates by molecular beam epitaxy. Here, the ultrathin Fe layer is the voltage-controlled free layer with perpendicular magnetic easy axis and top thick Fe layer is the reference layer with in-plane magnetic easy axis. The PMA energy, K_PMA and VCMA properties were evaluated from the normalized TMR curves measured under in-plane magnetic fields with various bias voltage applications. Saturation magnetization value was obtained by SQUID measurement.

High interface anisotropy energy, Kᵢ₀ of 2.1 mJ/m² was confirmed in our sample. Figure 1 shows an example of applied electric field dependence of surface anisotropy energy, K_PMA for the MTJ with tFe = 0.45 nm and tMgO = 2.8 nm. We observed large VCMA coefficient of about 400 fJ/Vm under the negative electric field application, while non-linear behavior appeared under the positive direction. In the presentation, we’ll discuss the possible origin of the enhanced VCMA effect and non-linearity including the evaluation results of structural analysis at the Cr/ultrathin Fe/MgO interfaces.
